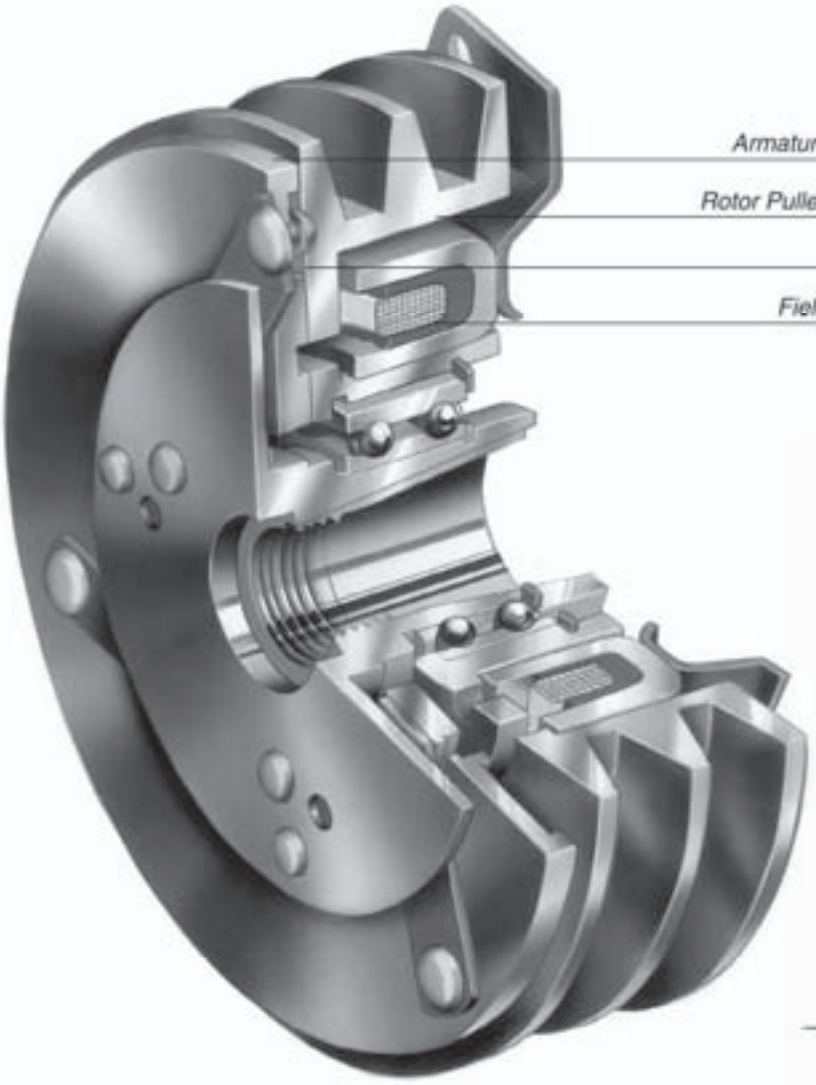
WARNER ELECTRIC

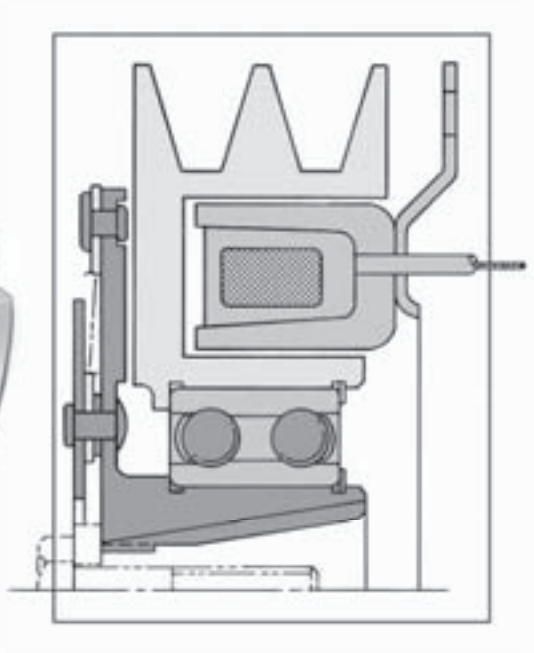
CLUTCHES

Engine, Pump and Compressor Power Take-Off Clutches

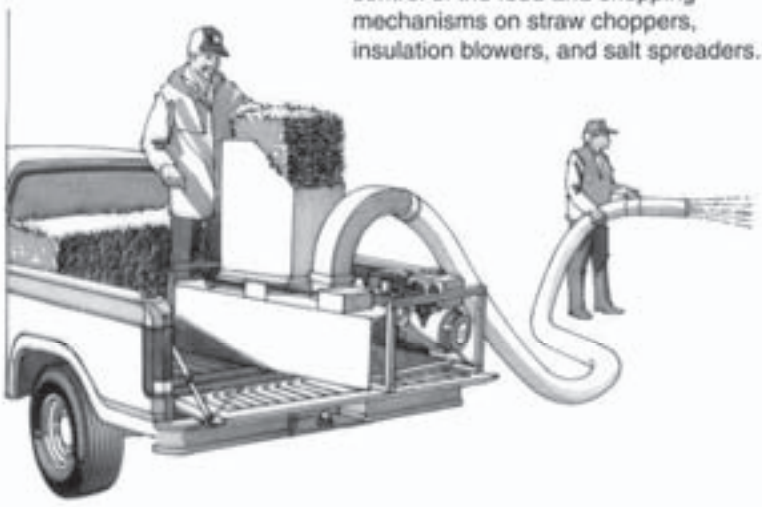
Warner Electric

Engine, Pump and Compressor Clutches—Selection

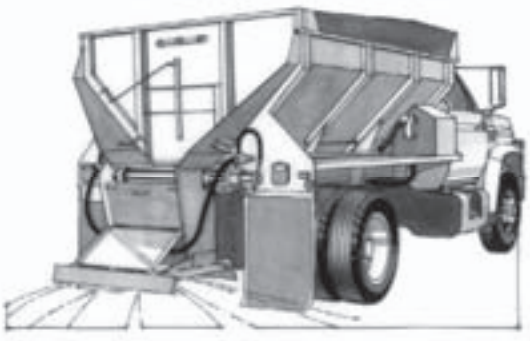




Electric clutches provide for remote control of the feed and chopping mechanisms on straw choppers, insulation blowers, and salt spreaders.



An engine mounted pump on this highway maintenance truck supplies hydraulic pressure for the sand spreader. Mounting an electric clutch on the pump will increase equipment life, improve machine efficiency, and allow the operator to engage and disengage the hydraulic system on demand.



Engine, Pump and Compressor Clutches—Selection

The right clutch for your application

Several specifications must be determined to select the right Warner Electric clutch for a particular application. Compile these from the selection factors discussed on the next four pages and compare them to the clutch specifications found on pages 6 through 23 to find the correct clutch for your application.

Clutch Dimensions

Overall or envelope dimensions of a clutch being considered for an application must be noted to ensure that the clutch will fit into the space allotted.

Choosing the correct size clutch

Torque and horsepower calculations are important in choosing the right clutch for your application.

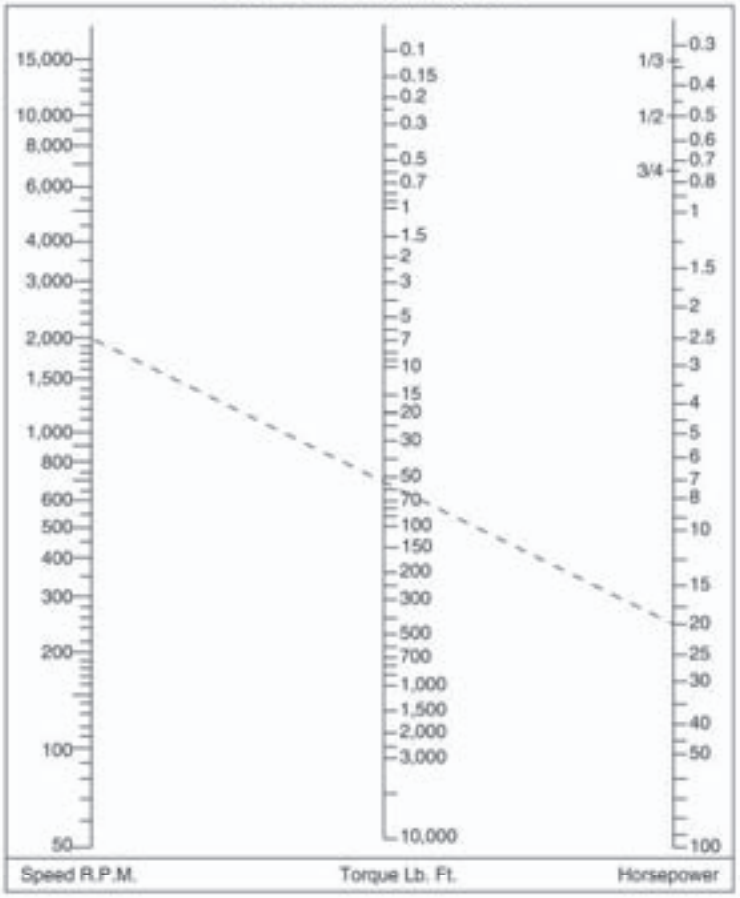
Two important factors needed to determine the static torque required for an application are the driven machine's horsepower and clutch operating speed. Locate horsepower and clutch RPM on their respective columns in the accompanying chart. Draw a straight line between the two points. The torque is the numerical value read from where this line intersects the TORQUE column. This number must be multiplied by a known service factor "K" from the data below to obtain the correct torque requirement for the clutch.

Service Factor "K"

The power pulses of a gasoline or diesel engine result in momentary torque output which is several times higher than the engine's rated torque. Many electric motors can also deliver up to three times their rated output for a short period. A clutch coupled to these power systems must be able to transmit the required torque for these short periods without slipping. Using the chart at right, estimate the "K" service factor which is appropriate for your application.

Torque Determination Chart

Horsepower / Nomograph



Type of Application	"K" Range
Conveyor and augers where a static load must be started by the dynamic torque of the clutch.	K = 3 to 5
Hydraulic pumps where the clutch may have to work against pressure at time of engagement	K = 2.5 to 5
Gasoline or diesel engines where the clutch should be able to stall the engine.	K = 2 to 5
Air compressors	K = 2 to 4
Electric motors where the clutch should be able to stall the motor. Use the overload factor from the motor catalog or use	K = 2 to 3
Light machines where the load is applied after the clutch is engaged. (e.g. a lathe)	K = 1.5 to 2.5

Example

A 10 horsepower pump driven by an electric motor operates at 1500 RPM. Using 3 as the value of the "K" factor, determine the required clutch torque capacity.

10 HP at 1500 RPM = 35 lb.ft. torque
"K" factor 3 x 40 lb.ft. = 105 lb.ft. torque.

This application will require a clutch with a static torque rating of 105 lb.ft.

Static torque can also be calculated by using the following formula:

$$T = \frac{5250 \times HP \times K}{RPM}$$

Example

A truck mounted hydraulic pump requires 8 horsepower to operate at 2000 RPM. What is the required clutch torque rating?

Using a service factor of 5:

$$T = \frac{5250 \times 8 \times 5}{2000}$$

T = 105 lb.ft.

A clutch with a static torque capacity of 105 lb.ft. is required for this application.

Fluid Power Formulae

$$T = \frac{HP \times 5250 \times K}{RPM}$$

$$T = \frac{CIR \times PSI}{75.4}$$

Where:

T= Torque (lb.ft.)
HP = Horsepower
RPM = Speed of Clutch (revolutions per minute)
CIR = Cubic inch per revolution (hydraulic pump)
PSI = Pounds per square inch
"K" = Service factor (see chart on page 2)

If HP is unknown:

$$HP = \frac{GPM \times PSI \times .000583}{\text{Pump efficiency}}$$

Where:

GPM = Fluid flow in gallons per minute
PSI = Pressure in pounds per square inch
Pump efficiency = normally 85%

Rule of Thumb:

1 HP per gallon @ 1500psi
.7 HP per gallon @ 1000psi

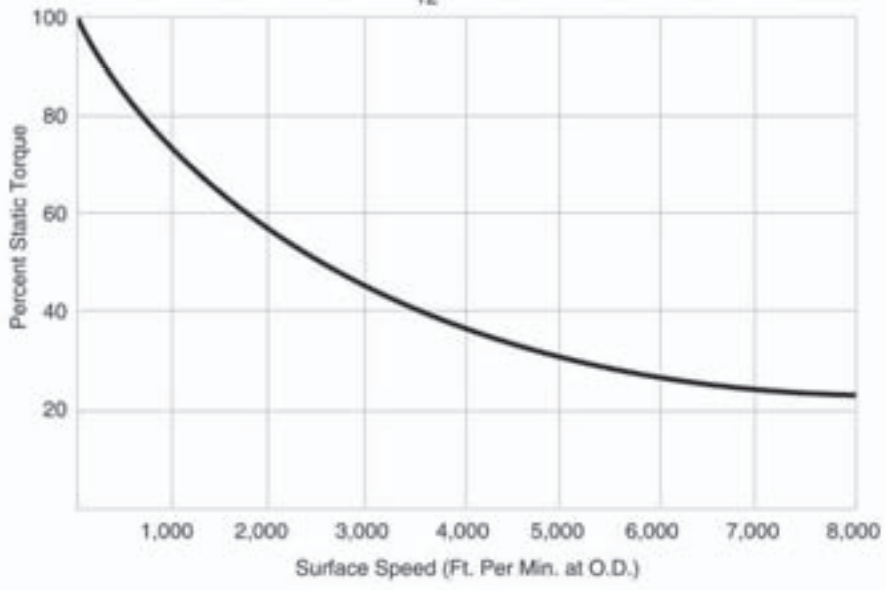
If PSI is unknown:

1 cubic inch per revolution equals 16 lb.in. of torque per 100 psi.
1 gallon equals 231 cubic inches.

TYPICAL DYNAMIC TORQUE

Dynamic Torque as Percent of Static Torque

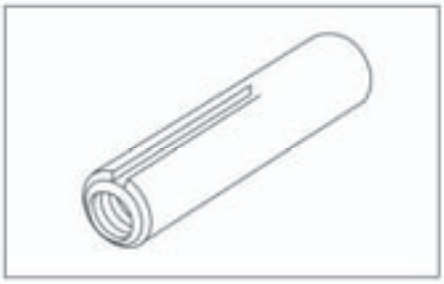
$$FPM = RPM \times \frac{3.14}{12} \times \text{Diameter (of clutch)}$$



Engine, Pump and Compressor Clutches—Selection

Shafts

Warner Electric standard clutches are available to adapt to three different shaft configurations:



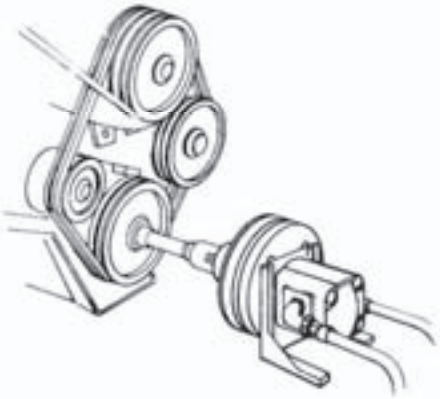
Straight bore - for through shaft or end of shaft mounting.

Tapered bore (8:1) - shaft tapers 1 1/2 inches per foot, for end of shaft mounting.

Tapered bore (4:1) - shaft tapers three inches per foot, for end of shaft mounting.

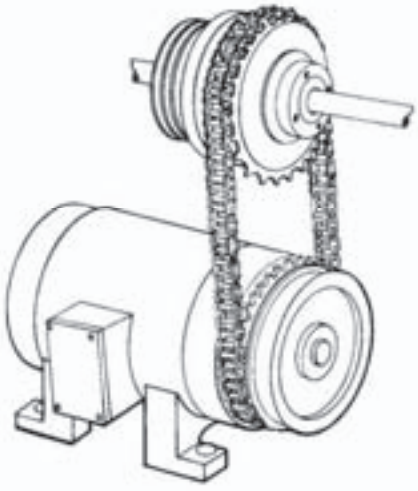
Types of Drives

Warner Electric offers clutches which are compatible with the three basic types of drives.



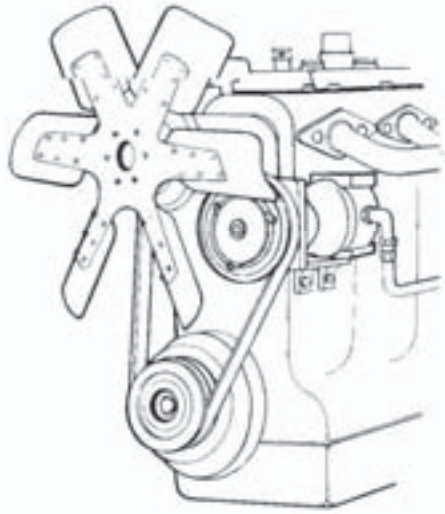
Direct Drive

In direct drive arrangements, a drive shaft with a universal joint or other flexible coupling is attached to the engine crankshaft or transmission PTO on one end and the pump or compressor on the other. The clutch usually mounts on the pump or compressor. The "yoke drive" clutches in this section are equipped with flanges designed to bolt directly to a universal joint assembly. **Drive shaft alignment must be within 3°.**



Parallel Shaft

In parallel shaft applications, torque is transmitted from a drive or line shaft to the pump, compressor or other accessory which is mounted parallel to it. The straight bore clutches with bearing mounted fields are often used in this drive arrangement. Belt or chain drives are most frequently used in parallel shaft applications.



Belt Drive

The most common method of driving mobile accessories is through automotive or industrial belts. The driven accessory is parallel to and driven by a pulley mounted on the engine crankshaft. The relative diameters of the drive and driven pulleys, speed range of the engine, and required pump or compressor performance are all factors to be considered when selecting a belt driven clutch. Warner Electric clutches have AB grooved pulleys, which permit the use of either an A or B V-belt.

Electrical

Electrical Ratings

All current and resistance ratings are taken at ambient temperatures of 70°F (20°C).

Voltage Requirements

Warner Electric clutches are normally furnished with 12 VDC coils. Clutches can be designed to accommodate other voltages.

Current Draw

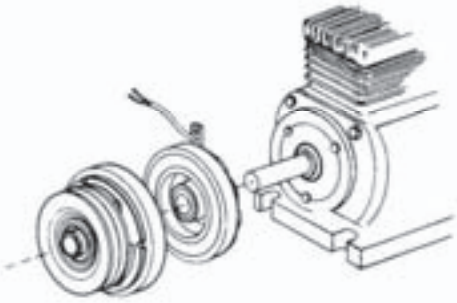
Current draw for each clutch model is listed in the product specifications section of this section.

Resistance/Heat Dissipation

Electrical resistance increases with coil temperature. Since the increase in electrical resistance reduces coil current, the torque transmitted by the clutch will be reduced. In applications where heat dissipation from the clutch is not adequate, air from an external source should be forced over the clutch to ensure proper operation. Most Warner Electric clutches shown in this section have been designed to operate in typical under hood temperatures.

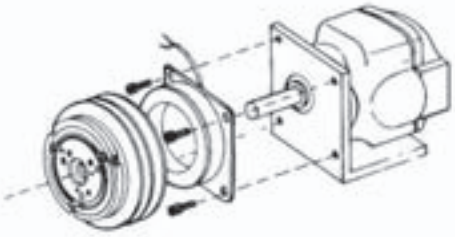
Clutch Mounting

Warner Electric clutches are offered with flange or bearing mounts. Select the type best suited for your application based on the information below.



Bearing Mounted Clutches

Bearing mounted clutches are pre-assembled into a complete operating unit which is mounted directly to the shaft. In this design, the field is mounted on its own bearing as an internal part of the clutch and has an antirotation tang to prevent it from turning in operation. This antirotation tang is to be pinned LOOSELY to a member or held with a torque arm.



Flange Mounted Clutches

In a flange mount clutch application, the field is bolted directly to a fixed member on either the output (engine crankcase or electric motor) or the driven accessory (input). Mounting brackets and fixtures for a specific application must be designed in accordance with the clutch dimensions found in the specifications section to ensure proper perpendicularity and concentricity.

Clutch Location

Wherever possible, the clutch should be located on the higher speed shaft.

Clutch Rotation

Direction of drive can be a significant design consideration in applications with a peak load during clutch engagement. Warner Electric clutches incorporate leaf springs in the armature to transmit the load. When peak loads at start-up are possible, springs should be oriented so that they are placed in tension (stretch).

Clutch rotation can be determined by observing the leaf spring direction on the armature.

Glossary

Acceleration Time, Engagement Time

The time required to change the speed of a system from the moment the clutch receives the appropriate electrical signal until the clutch is fully engaged and the system is moving at its maximum speed.

Bearing Mount

A clutch which is preassembled into a complete operating unit and is mounted directly to the shaft.

Brushholder

A clutch component which carries electrical current from the lead wires to the rotating magnet.

Build Up Time

The time in seconds required to build up to 90% of rated flux which corresponds to 80% rated torque.

Burnishing

The process of cycling or "wearing in" of clutch or brake friction surfaces. This process ensures rated torque during initial cycles, and decreases the cycles required from installation to full rated torque output.

Decay Time

The time in seconds required to decay to 10% of rated flux which corresponds to 1% of rated torque on de-energization of the unit.

Deceleration Time, Engagement Time

The time required to stop a system from the moment the brake receives the appropriate electrical signal until the brake is statically engaged and the system is at rest.

Field

A component part of Warner Electric clutches consisting of a steel shell and a coil. Also referred to as a magnet.

Flange Mount

A clutch which has the field bolted directly to a fixed member on the machine.

Flux

Magnetic attraction caused by an electrical current.

Gap

The distance between armature and rotor faces in clutches when the unit is in an inactive state (i.e. disengaged).

Integral Key

A key shaped directly into the bore of a clutch. This is sometimes used in place of a standard keyway and key.

K Factor

See service factor.

Poles

1. Refers to magnet poles: North/South poles. 2. The edges of a Warner Electric magnet or field shell through which the magnetic flux flows.

Pulley

A sheave that turns or is turned by a belt so as to transmit torque, rotation.

Residual Magnetism

The condition in magnets where low level magnetism remains after the electric current is removed.

Rotor

The input member of a clutch/brake.

Service Factor

A figure by which torque is multiplied to ensure performance of the clutch under the worst case application conditions.

Tapered Bore (Shaft)

Many hydraulic pumps incorporate a taper on the output shaft, providing stronger clutch-to-shaft engagement than on straight shafts. Tapered shafts are most commonly in 4:1 and 8:1 taper ratios.

4:1 Taper: The shaft changes in diameter by one inch for each four inches of length.

8:1 Taper: The shaft changes in diameter by one inch for each eight inches of length.

Torque

Static: The torque which is developed when there is no relative motion or slippage between the mating friction surfaces. A clutch which is fully engaged and driving exhibits static torque. All standard units are rated on the basis of static torque after burnishing.

Dynamic: The torque developed when there is relative motion between the mating friction surface. The torque varies inversely with the amount of slip, so specific values must be taken from engineering data.

Clutch Location

Wherever possible, the clutch should be located on the higher speed shaft.

Clutch Rotation

Direction of drive can be a significant design consideration in applications with a peak load during clutch engagement. Warner Electric clutches incorporate leaf springs in the armature to transmit the load. Where peak loads at start-up are possible, springs should be oriented so that they are placed in tension (or stretch).

Spring rotation can be determined by observing the leaf spring direction on the armature.

Electrical Ratings

All current and resistance ratings are taken at ambient temperatures of 70F (20C).

Fluid Power Formulae

If you are sizing a clutch for a pump application, but do not know the HP required, the following formula will allow you to work back to the torque formulae.

If HP is unknown:

$$HP = \frac{GPM \times PSI \times .000583}{\text{Pump Efficiency}}$$

Where:

GPM = Fluid flow in gallons per minute.

PSI = Pressure in pounds per square inch.

Pump Efficiency = normally 85%.

Rules of Thumb

1 HP per gallon @ 1500 psi

.7 HP per gallon@ 1000 psi

If PSI is unknown:

1 cubic inch per revolution equals 16 lb.in. of torque per 100 psi.

1 gallon equals 231 cubic inches.

If GPM is unknown:

$$GPM = \frac{RPM \times DISP\ (IN^3)}{231}$$

Static Torque

The torque requirements for your particular application may be determined by using the following relationship:

$$T = \frac{5250 \times HP}{RPM}$$

$$T = \frac{CIR \times PSI}{75.4}$$

Voltage Requirements

Most clutches and clutch/brakes require 12 VDC to operate at their maximum torque rating. Less than 12 VDC may cause clutch slippage and premature failure.

Abbreviations:

T = Torque

HP = Horsepower

RPM = Speed of clutch (Revolutions per minute)

CIR = Cubic inch per revolution

PSI = Pounds per square inch

K = Service factor
